## **Searching Algorithms**

Lectures prepared by: Dr. Manal Alharbi, and Dr. Areej Alsini

# Review: Searching Problem

- Assume  $A$  is an array with  $n$  elements  $A[1], A[2], \dots, A[n]$ . For a given element  $x$ , we must determine whether there is an index  $j$ ;  $1 \leq j \leq n$ , such that  $x = A[j]$
- Two algorithms, among others, address this problem
  - Linear Search
  - Binary tree: Binary Search

# Linear Search Algorithm

**Algorithm:** LINEARSEARCH

**Input:** array  $A[1..n]$  of  $n$  elements and an element  $x$ .

**Output:**  $j$  if  $x = A[j]$ ,  $1 \leq j \leq n$ , and 0 otherwise.

1.  $j = 1$
2. **while**  $(j \leq n)$  **and**  $(x \neq A[j])$  **do**
3.      $j = j + 1$
4. **end while**
5. **if**  $x = A[j]$  **then return**  $j$  **else return** 0

# Analyzing Linear Search

- One way to measure efficiency is to count how many statements get executed before the algorithm terminates
- One should keep an eye, though, on statements that are executed “repeatedly”.
- What will be the number of “element” comparisons if  $x$ 
  - First appears in the first element of  $A$
  - First appears in the middle element of  $A$
  - First appears in the last element of  $A$
  - Doesn't appear in  $A$ .

# Analyzing Linear Search

- One way to measure efficiency is to count how many statements get executed before the algorithm terminates
- One should keep an eye, though, on statements that are executed “repeatedly”.
- What will be the number of “element” comparisons if  $x$ 
  - First appears in the first element of  $A$  1 comparison
  - First appears in the middle element of  $A$   $\frac{n}{2}$  comparisons
  - First appears in the last element of  $A$   $n$  comparisons
  - Doesn't appear in  $A$ .  $n$  comparisons

# Analyzing Linear Search

We are interested here in **finding the number of element comparisons** .In the algorithm, element comparisons are done in the while statement (Step 2) of the algorithm, that is

**2. while ( $j \leq n$ ) and ( $x \neq A[j]$ )**

**The minimum number of comparisons occurs** when **the element** we are looking for **is the first element in the array**. In this case, there is only one element comparison.

**The maximum number of element comparisons occurs** when **the element is not among the elements of the array or in the last index**. This results in n comparisons.

**Thus, the number of element comparisons in the linear search algorithm is between 1 and n inclusive.**

# Linear Search Algorithm

**Algorithm:** LINEARSEARCH

**Input:** array  $A[1..n]$  of  $n$  elements and an element  $x$ .

**Output:**  $j$  if  $x = A[j]$ ,  $1 \leq j \leq n$ , and 0 otherwise.

Algorithm	Cost	Time
1. $j = 1$	$c_1$	1
2. <b>while</b> $(j \leq n)$ <b>and</b> $(x \neq A[j])$ <b>do</b>	$c_2$	$K$
4. $j = j + 1$	$c_3$	$K - 1$
5. <b>end while</b>		
6. <b>if</b> $x = A[j]$ <b>then</b>	$c_6$	1
7. <b>return</b> $j$	$c_7$	1
8. <b>else return</b> 0	$c_8$	1

- $K$  ranges between 1 and  $n$ .
- Worst-case time =  $n + n - 1 = 2n - 1$
- Total time complexity =  $\mathbf{O(2n - 1) = O(n)}$

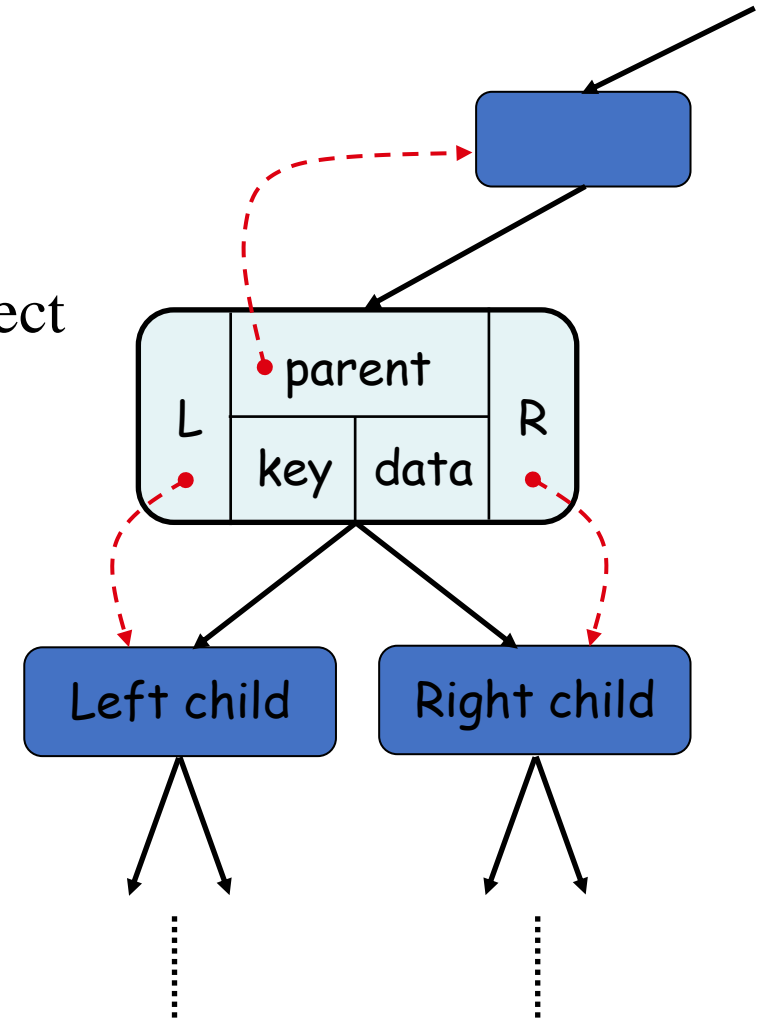

# Can we do better? Review: binary tree- concept

- Yes, using **binary search**.
- **Algorithms Design: Divide-and-conquer**
  - Let  $\pi$  be any problem with  $|\pi| = n$ . To solve using divide-and-conquer the following steps are involved:
    - Generate  $k$  subproblems from  $\pi$  (for some  $k \geq 1$ ).
      - Let these subproblems be  $\pi_1, \pi_2, \dots, \pi_k$ ;
    - for  $i = 1$  to  $k$  do
      - Recursively (or otherwise) solve  $\pi_i$ ;
    - Combine the solutions obtained in step 2 to create a solution for  $\pi$ .
  - A classical example of **divide-and-conquer** is **binary search**. For this problem, the input are a sorted sequence  $X = k_1, k_2, \dots, k_n$  and another element  $x$ . The problem is to check if  $x \in X$ .

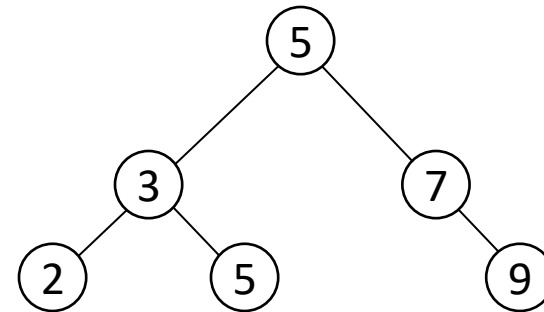

# Binary Search Trees- Review

- Tree representation:
  - A linked data structure in which each node is an object
- Node representation:
  - **Key** field
  - **Left**: pointer to left child
  - **Right**: pointer to right child
  - **p**: pointer to parent ( $p[\text{root}[T]] = \text{NIL}$ )
- Satisfies the binary-search-tree property !!

# Binary Search Tree Property

- Binary search tree property:
  - If  $y$  is in left subtree of  $x$ ,  
then  $\text{key}[y] \leq \text{key}[x]$
  - If  $y$  is in right subtree of  $x$ ,  
then  $\text{key}[y] \geq \text{key}[x]$

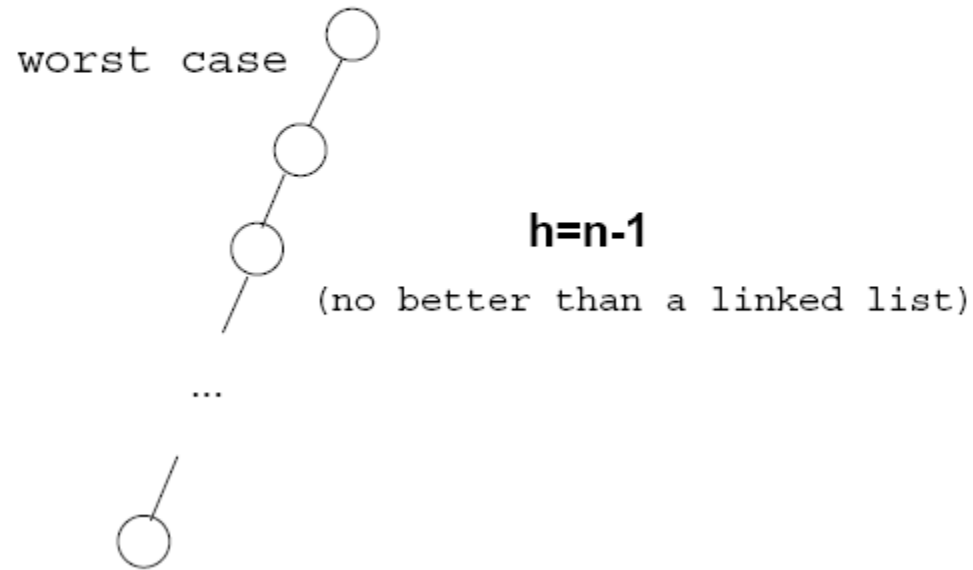

# Binary Search Trees

- Support many dynamic set operations
  - SEARCH, MINIMUM, MAXIMUM, PREDECESSOR, SUCCESSOR, INSERT, DELETE
- Running time of basic operations on binary search trees
  - On average:  $\Theta(\log n)$ 
    - The expected height of the tree is  $\log n$
  - In the worst case:  $\Theta(n)$ 
    - The tree is a linear chain of  $n$  nodes

# Worst Case

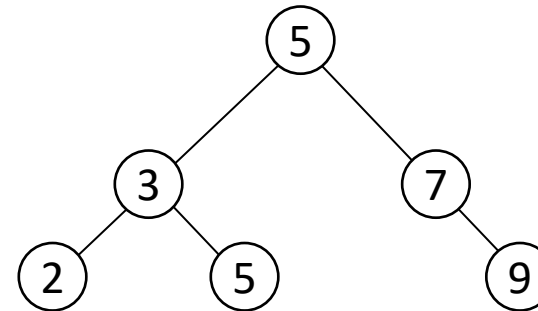

- If the tree is very **unbalanced**, then running time will be  $O(n)$ .

# Traversing a Binary Search Tree

- **Inorder** tree walk:
  - Root is printed between the values of its left and right subtrees **left, root, right**
  - Keys are printed in **sorted order**
- **Preorder** tree walk:
  - root printed first: **root, left, right**
- **Postorder** tree walk:
  - root printed last: **left, right, root**

Example:

Inorder: 2 3 5 5 7 9

Preorder: 5 3 2 5 7 9

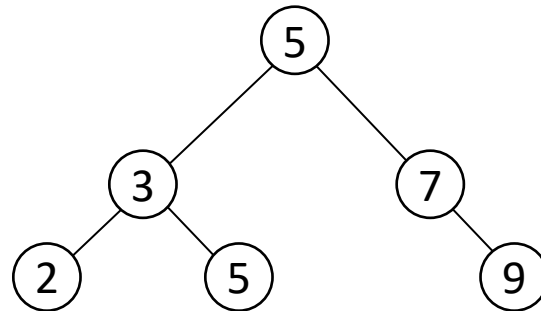

Postorder: 2 5 3 9 7 5

# Traversing a Binary Search Tree

*Alg:* INORDER-TREE-WALK( $x$ )

1.   **if**  $x \neq \text{NIL}$
2.     **then** INORDER-TREE-WALK (  $\text{left } [x]$  )
3.         print  $\text{key } [x]$
4.     INORDER-TREE-WALK (  $\text{right } [x]$  )

• *E.g.:*

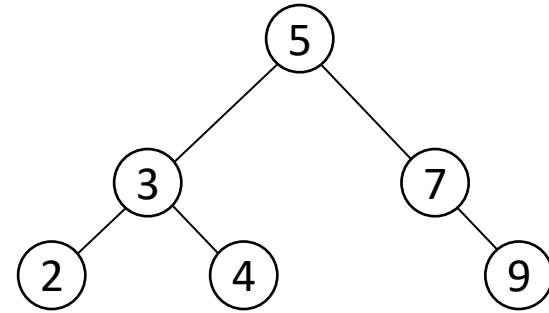

Output: 2 3 5 5 7 9

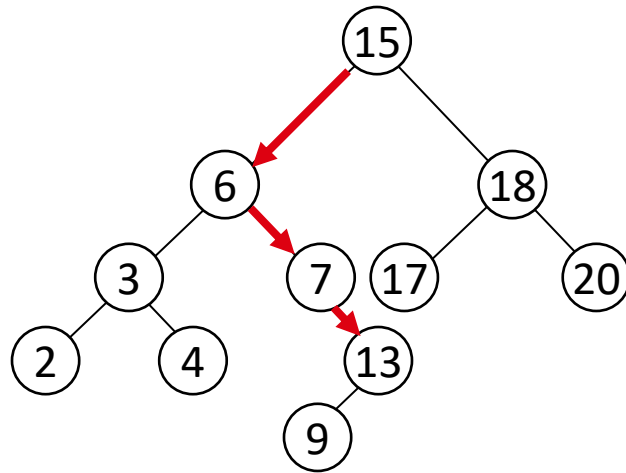

- Running time:
  - $\Theta(n)$ , where  $n$  is the size of the tree rooted at  $x$

# Searching for a Key

- Given a pointer to the root of a tree and a key  $k$ :
  - Return a pointer to a node with key  $k$  if one exists
  - Otherwise return NIL
- Idea
  - Starting at the root: trace down a path by comparing  $k$  with the key of the current node:
    - If the keys are equal: we have found the key
    - If  $k < \text{key}[x]$  search in the left subtree of  $x$
    - If  $k > \text{key}[x]$  search in the right subtree of  $x$

# Example: TREE-SEARCH

- Search for key 13:
  - $15 \rightarrow 6 \rightarrow 7 \rightarrow 13$

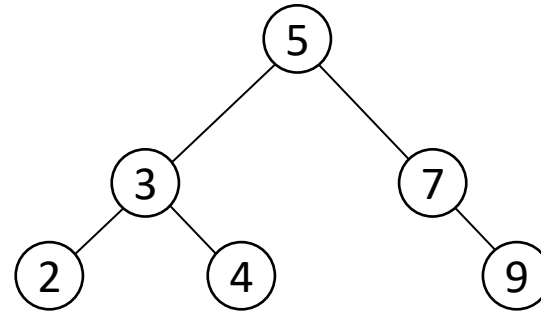

# Searching for a Key

*Alg:* TREE-SEARCH( $x$ ,  $k$ )

1. **if**  $x = \text{NIL}$  or  $k = \text{key}[x]$
2.       **then return**  $x$
3. **if**  $k < \text{key}[x]$
4.       **then return** TREE-SEARCH(left  $[x]$ ,  $k$  )
5.       **else return** TREE-SEARCH(right  $[x]$ ,  $k$  )

Running Time:  $O(h)$ ,  
 $h$  – the height of the tree

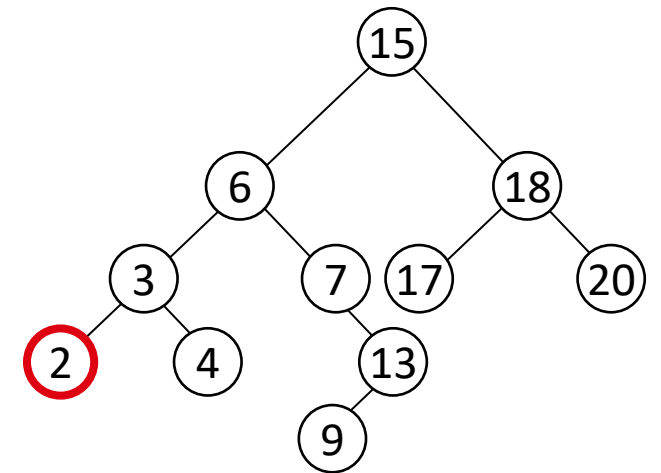

# Finding the Minimum in a Binary Search Tree

- Goal: find the minimum value in a BST
  - Following left child pointers from the root, until a NIL is encountered

*Alg:* TREE-MINIMUM( $x$ )

1. **while**  $\text{left}[x] \neq \text{NIL}$
2.       **do**  $x \leftarrow \text{left}[x]$
3. **return**  $x$

Running time:  $O(h)$ ,  $h$  – height of tree

Minimum = 2

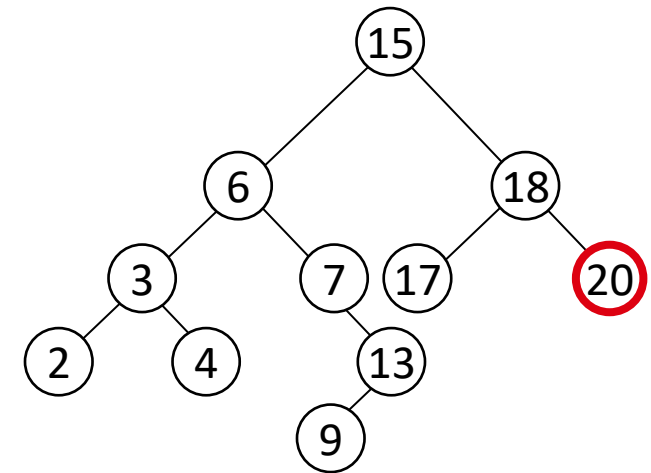

# Finding the Maximum in a Binary Search Tree

- Goal: find the maximum value in a BST
  - Following right child pointers from the root, until a NIL is encountered

*Alg:* TREE-MAXIMUM( $x$ )

1. **while** right [ $x$ ]  $\neq$  NIL
2.       **do**  $x \leftarrow$  right [ $x$ ]
3. **return**  $x$

- Running time:  $O(h)$ ,  $h$  – height of tree

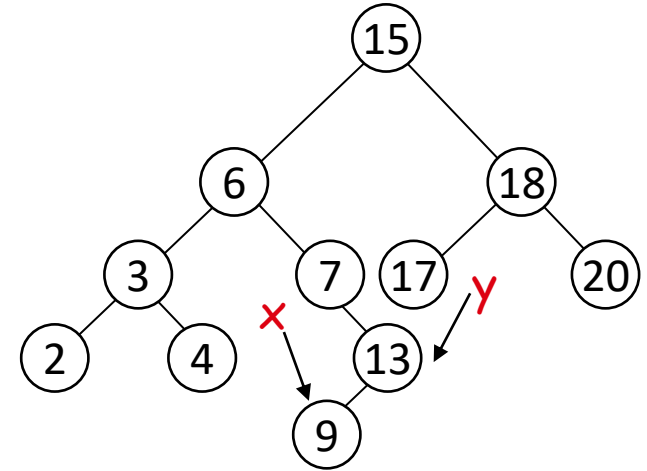

Maximum = 20

# Successor

*Def:*  $\text{successor}(x) = y$ , such that  $\text{key}[y]$  is the smallest key  $> \text{key}[x]$

- *E.g.:*  $\text{successor}(15) = 17$   
 $\text{successor}(13) = 15$   
 $\text{successor}(9) = 13$

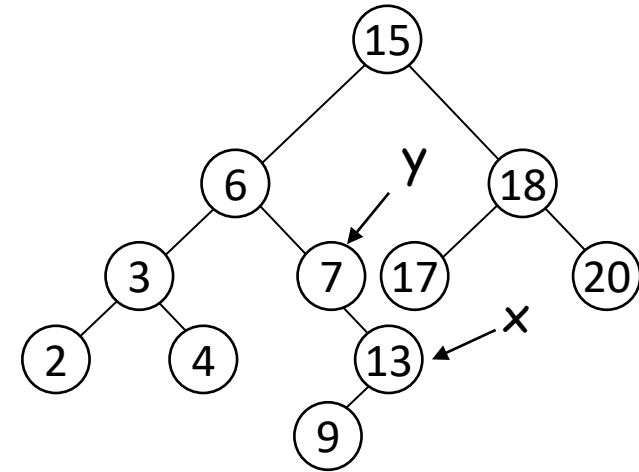

- Case 1:  $\text{right}(x)$  is nonempty
  - $\text{successor}(x)$  = the minimum in  $\text{right}(x)$
- Case 2:  $\text{right}(x)$  is empty
  - go up the tree until the current node is a left child:  
 $\text{successor}(x)$  is the parent of the current node
  - if you cannot go further (and you reached the root):  
 $x$  is the largest element

# Finding the Successor

*Alg:* TREE-SUCCESSOR( $x$ )

1. **if** right [ $x$ ]  $\neq$  NIL
2.     **then return** TREE-MINIMUM(right [ $x$ ])
3.  $y \leftarrow p[x]$
4. **while**  $y \neq$  NIL and  $x =$  right [ $y$ ]
5.     **do**  $x \leftarrow y$
6.      $y \leftarrow p[y]$
7. **return**  $y$

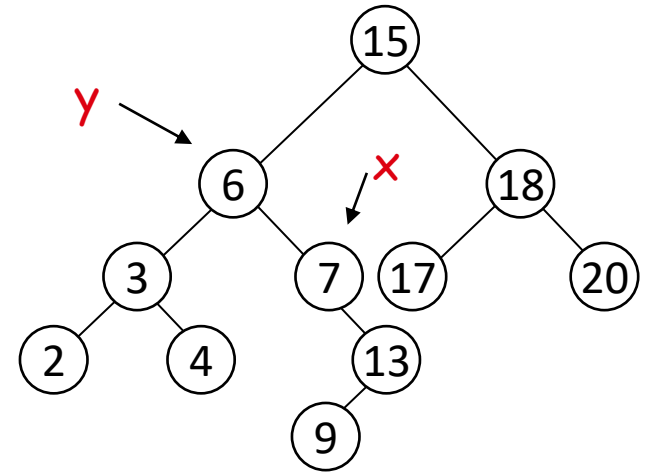

Running time:  $O(h)$ ,  $h$  – height of the tree

# Predecessor

*Def:*  $\text{predecessor}(x) = y$ , such that  $\text{key}[y]$  is the biggest  $\text{key} < \text{key}[x]$

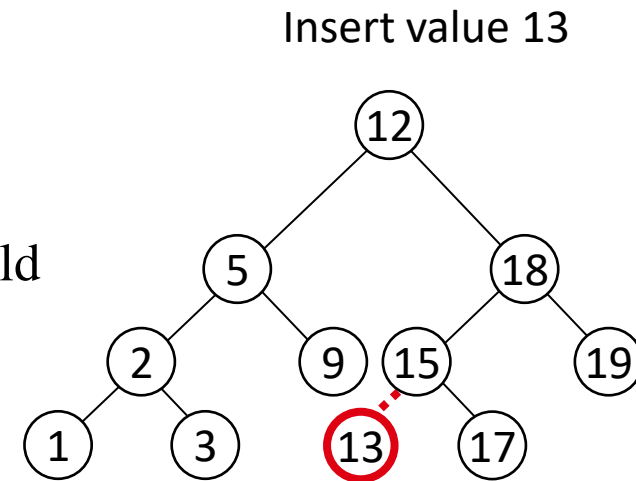

- *E.g.:*  $\text{predecessor}(15) = 13$   
 $\text{predecessor}(9) = 7$   
 $\text{predecessor}(7) = 6$

- Case 1:  $\text{left}(x)$  is nonempty
  - $\text{predecessor}(x)$  = the maximum in  $\text{left}(x)$
- Case 2:  $\text{left}(x)$  is empty
  - go up the tree until the current node is a right child:  
 $\text{predecessor}(x)$  is the parent of the current node
  - if you cannot go further (and you reached the root):  
 $x$  is the smallest element

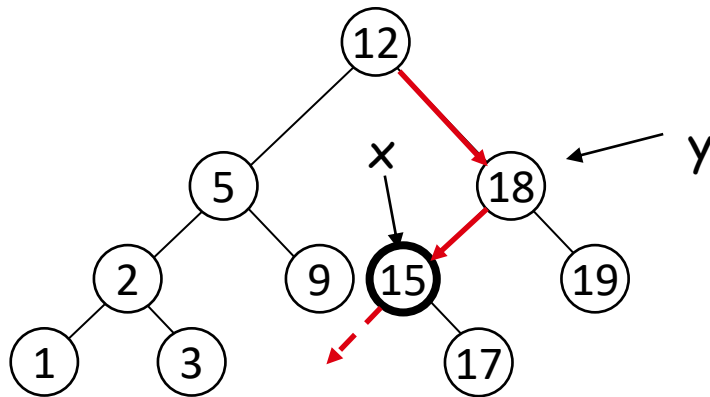

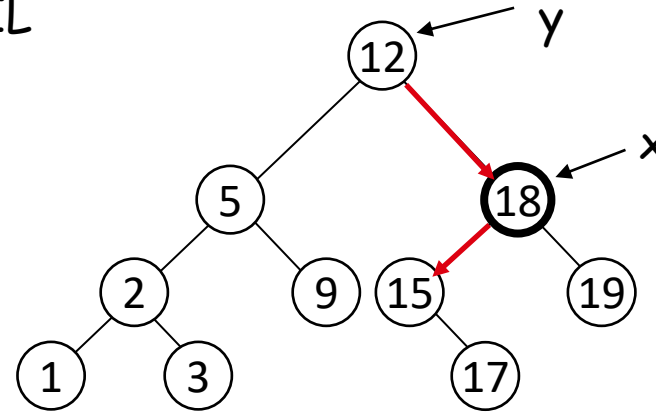

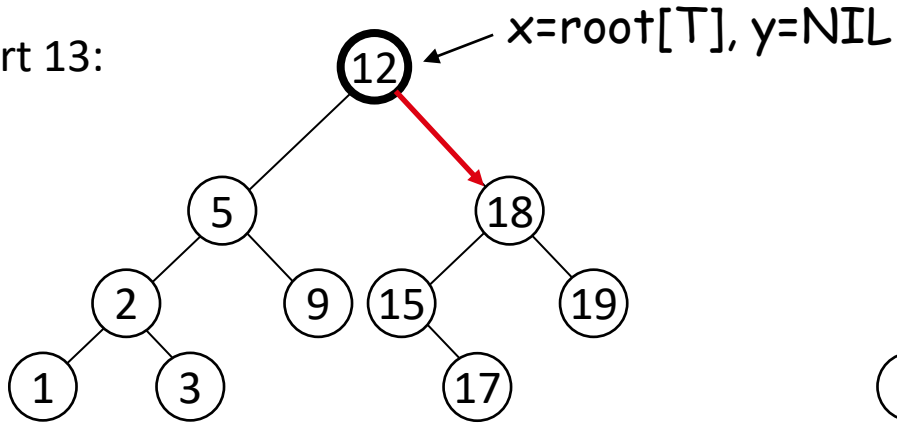

# Insertion

- Goal:
  - Insert value  $v$  into a binary search tree
- Idea:
  - If  $\text{key}[x] < v$  move to the right child of  $x$ ,  
else move to the left child of  $x$
  - When  $x$  is NIL, we found the correct position
  - If  $v < \text{key}[y]$  insert the new node as  $y$ 's left child  
else insert it as  $y$ 's right child
- Beginning at the root, go down the tree and maintain:
  - Pointer  $x$  : traces the downward path (current node)
  - Pointer  $y$  : parent of  $x$  (“trailing pointer”)

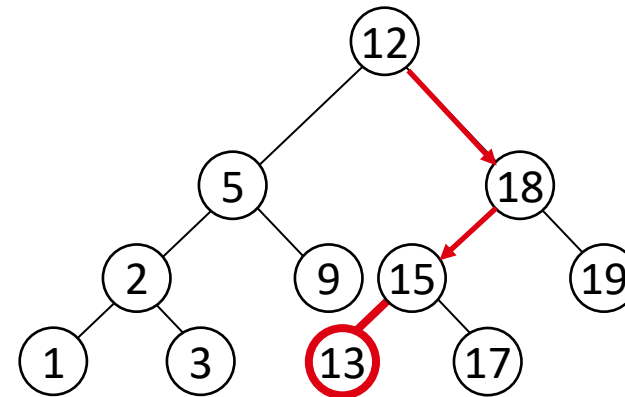

# Example: TREE-INSERT

Insert 13:

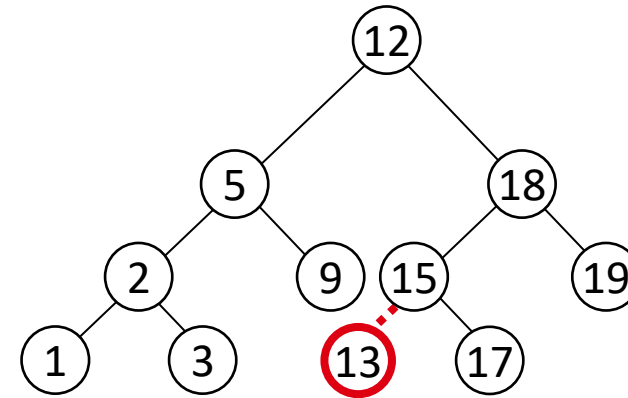

$x = \text{NIL}$   
 $y = 15$

## *Alg:* TREE-INSERT( $T, z$ )

1.  $y \leftarrow \text{NIL}$
2.  $x \leftarrow \text{root}[T]$
3. **while**  $x \neq \text{NIL}$
4.     **do**  $y \leftarrow x$
5.         **if**  $\text{key}[z] < \text{key}[x]$
6.             **then**  $x \leftarrow \text{left}[x]$
7.             **else**  $x \leftarrow \text{right}[x]$
8.  $p[z] \leftarrow y$
9. **if**  $y = \text{NIL}$
10.     **then**  $\text{root}[T] \leftarrow z$
11.     **else if**  $\text{key}[z] < \text{key}[y]$
12.         **then**  $\text{left}[y] \leftarrow z$
13.         **else**  $\text{right}[y] \leftarrow z$

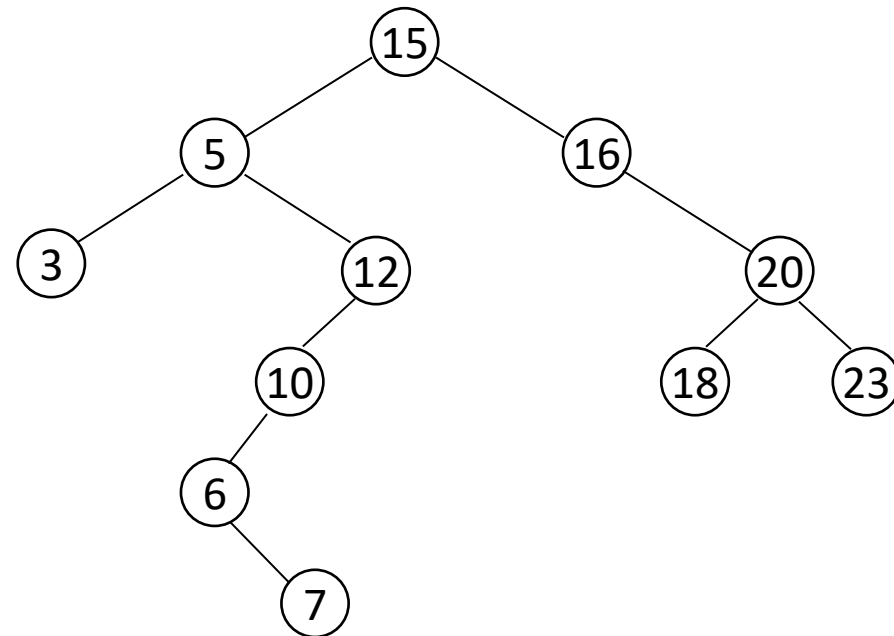

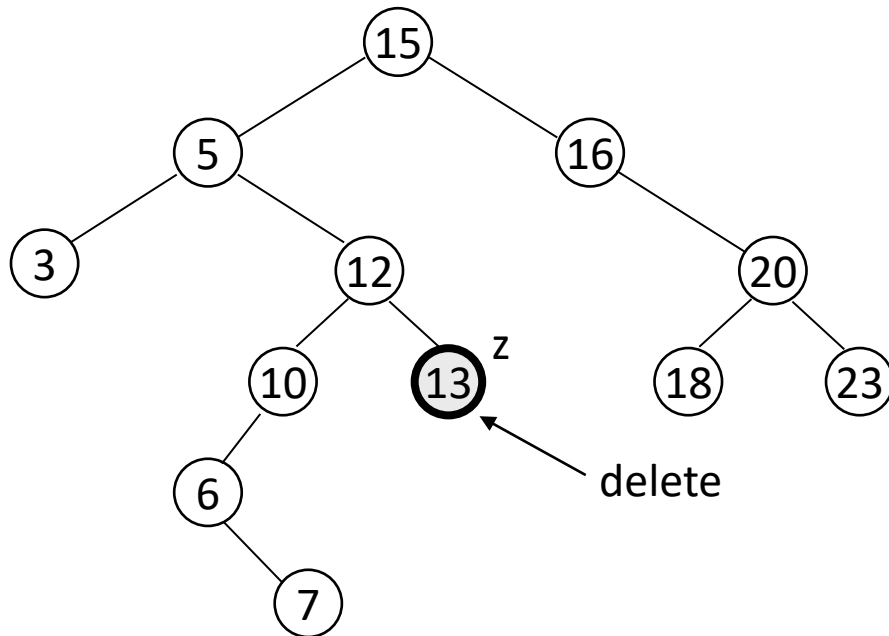

Tree  $T$  was empty

Running time:  $O(h)$

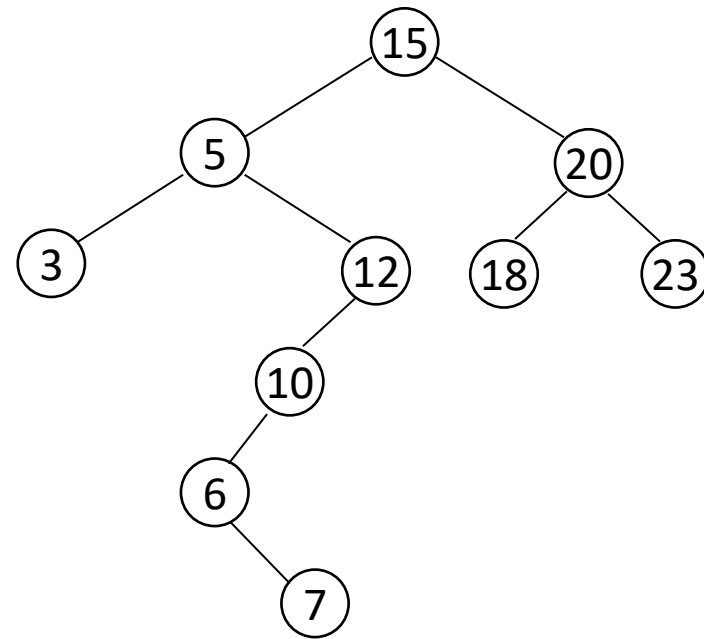

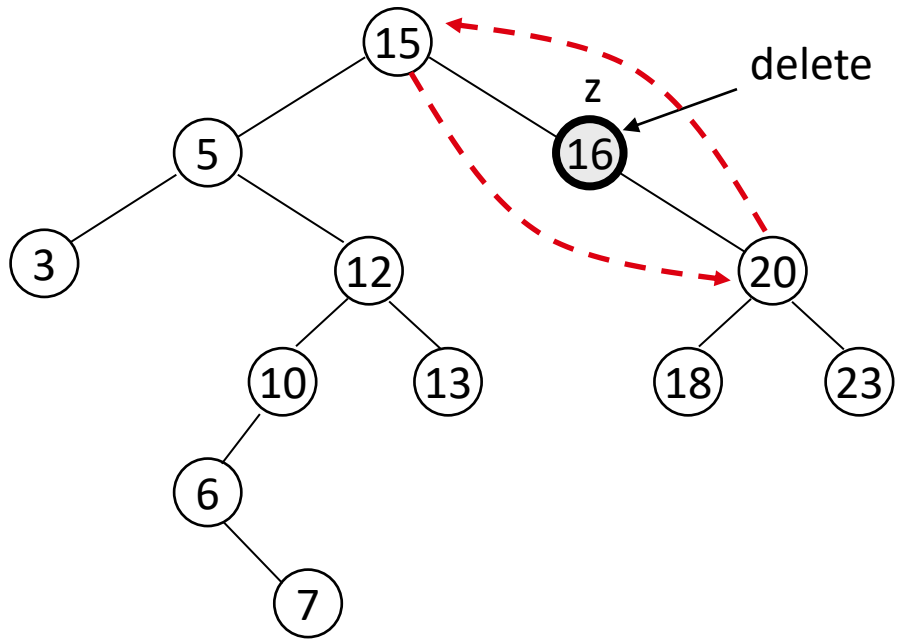

# Deletion

- Goal:
  - Delete a given node **z** from a binary search tree
- Idea:
  - **Case 1: z** has no children
    - Delete **z** by making the parent of **z** point to NIL

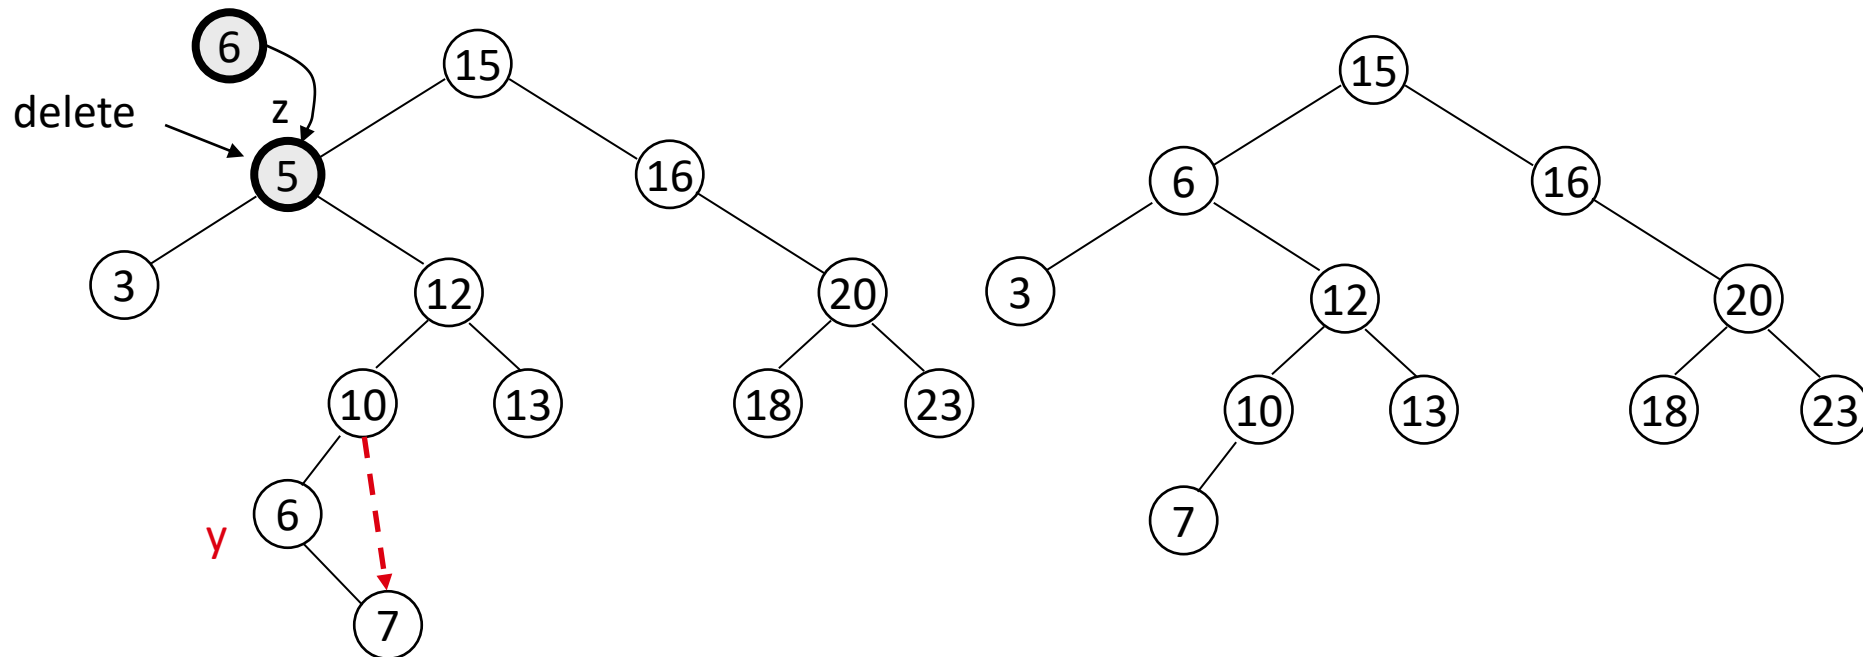

# Deletion

- **Case 2:  $z$  has one child**
  - Delete  $z$  by making the parent of  $z$  point to  $z$ 's child, instead of to  $z$

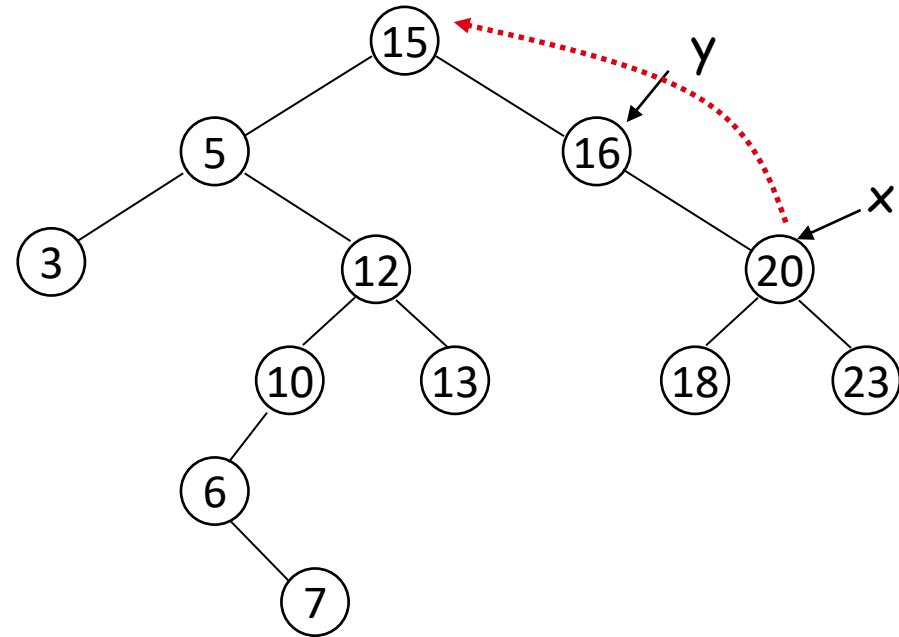

# Deletion

- **Case 3:  $z$  has two children**
  - $z$ 's successor ( $y$ ) is the minimum node in  $z$ 's right subtree
  - $y$  has either no children or one right child (but no left child)
  - Delete  $y$  from the tree (via Case 1 or 2)
  - Replace  $z$ 's key and satellite data with  $y$ 's.

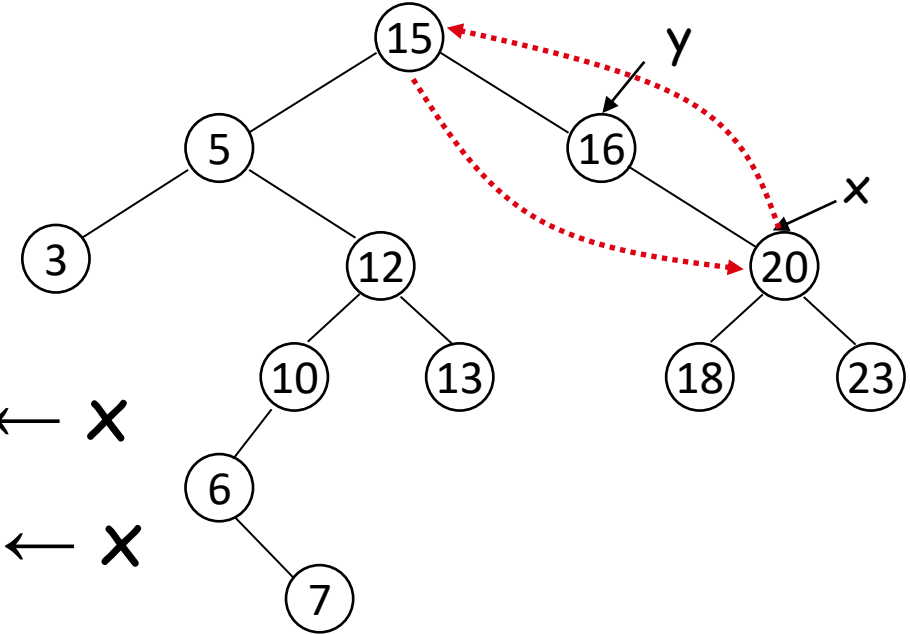

# TREE-DELETE( $\mathcal{T}, z$ )

1. **if**  $\text{left}[z] = \text{NIL}$  or  $\text{right}[z] = \text{NIL}$
2.   **then**  $y \leftarrow z$  z has one child
3.   **else**  $y \leftarrow \text{TREE-SUCCESSOR}(z)$  z has 2 children
4. **if**  $\text{left}[y] \neq \text{NIL}$
5.   **then**  $x \leftarrow \text{left}[y]$
6.   **else**  $x \leftarrow \text{right}[y]$
7. **if**  $x \neq \text{NIL}$
8.   **then**  $p[x] \leftarrow p[y]$

# TREE-DELETE( $T, z$ ) – cont.

9. **if**  $p[y] = \text{NIL}$
10.   **then**  $\text{root}[T] \leftarrow x$
11.   **else if**  $y = \text{left}[p[y]]$
12.       **then**  $\text{left}[p[y]] \leftarrow x$
13.       **else**  $\text{right}[p[y]] \leftarrow x$
14. **if**  $y \neq z$
15.   **then**  $\text{key}[z] \leftarrow \text{key}[y]$
16.       copy  $y$ 's satellite data into  $z$
17. **return**  $y$

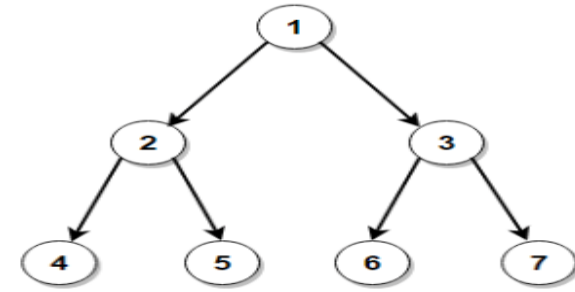

Running time:  $O(h)$

# Binary Search Trees - Summary

- Operations on binary search trees:
  - SEARCH  $O(h)$
  - PREDECESSOR  $O(h)$
  - SUCCESSOR  $O(h)$
  - MINIMUM  $O(h)$
  - MAXIMUM  $O(h)$
  - INSERT  $O(h)$
  - DELETE  $O(h)$
- These operations are fast if the height of the tree is **small** – otherwise their performance is similar to that of a linked list

# Theorem

- The number of comparisons performed by Algorithm **BINARY SEARCH** on a sorted array of size  $n$  is at most  $\lfloor \log n \rfloor + 1$
- **Proof:**
  - **Fact:** If  $T$  is a binary tree with  $n$  nodes whose height is  $h$ , then,

$$\underbrace{n}_{\text{max}} \geq h \geq \underbrace{\log(n+1)}_{\text{min}}.$$

- In a binary tree the **maximum number of nodes** we can have in level  $i$  is  $2^{i-1}$ .
- This implies that the maximum number of nodes we can have in a binary tree of height  $h$  is  $1 + 2 + 4 + \dots + 2^{h-1} = 2^h - 1$ .
- In other words,  $n \leq 2^h - 1 \rightarrow \log_2 n \leq h-1 \rightarrow h \geq \log_2 n + 1$
- The fact that  $h \leq n$  is easy to see. This happens when we have a skewed tree where each node (other than the leaf) has a single child.
- A binary tree is said to be *full* if every non-leaf has exactly two children and all the leaves are at the same level. A binary tree is defined to be *complete* if it is full except that there could be some nodes missing in the last level and the missing nodes in the last level (if any) are right justified. The height of a complete binary tree with  $n$  nodes is  $\Theta(\log n)$ .

# Binary Search

- We can do “better” than linear search if we knew that the elements of  $A$  are sorted, say in non-decreasing order (increasing order).
- As stated above, we are interested in determining whether a given element is among the list of elements stored in the array of size  $n$ .
- When the elements are sorted, we use a more efficient algorithm such as the binary search algorithm as follows:
  - Let  $A[low.. high]$  be a non-empty array of elements sorted in nondecreasing order and let  $A[mid]$  be the middle element.
  - The idea is that you can compare  $x$  to the middle element of  $A$ , say  $A[middle]$ .
    - If  $x > A[mid]$ :
      - We observe that If  $x$  is in  $A$ , then it must be one of the elements  $A[mid+1], A[mid+2], \dots, A[mid+ high]$
      - It follows that we only need to search for in  $A[mid+1... high]$ .
    - In other words, the entries in  $A[low...mid]$  are discarded.
    - Similarly, if  $x < A[mid]$ , then we only need to search for in  $A[low...mid-1]$
- This results in an efficient strategy, which is referred to as binary search.

**Example 1.** In this example, we will search for the element  $x = 35$  or any value  $> 35$  in an array of 14 elements. The array is assumed to be sorted in nondecreasing order with the values as shown.

Index:	1	2	3	4	5	6	7	8	9	10	11	12	13	14
$A[1..14] =$	1	4	5	7	8	9	10	12	15	22	23	27	32	35

The execution of the binary search algorithm on the above array proceeds as follows:

First, the index (referred to as *mid* in Algorithm BINARYSEARCH) of the array element to be compared with the value  $x$  is computed using the equation:

$$mid = \lfloor (low + high) / 2 \rfloor = \lfloor (1 + 14) / 2 \rfloor = 7$$

and the value  $x (=35)$  is compared with  $A[7] (= 10)$  and since  $35 > A[7]$ , the portion of the array  $A[1 .. 7]$  is discarded.

### Example 1 (Cont.)

Thus, the remaining portion of the array to be searched next is now reduced to the following subarray:

<b>Index:</b>	<b>8</b>	<b>9</b>	<b>10</b>	<b>11</b>	<b>12</b>	<b>13</b>	<b>14</b>
<b>A[8..14] =</b>	12	15	22	23	27	32	35

Next, we repeat the process of computing the index of the array element (among the remaining elements of the subarray A[8..14] ) to be compared with x. In this case, we use low = 8 and high =14, and get:

$$mid = \lfloor (low + high) / 2 \rfloor = \lfloor (8 + 14) / 2 \rfloor = 11$$

Then x is compared with A[11] (= 23) and since  $35 > A[11]$ , the portion of the array A[8..11] is discarded.

- **Example 1 (Cont.)**

- Finally, x is compared with A[14] (=35) as

$$mid = \lfloor (14 + 14)/2 \rfloor = 14$$

and hence the search is successively completed.

# Binary Search Algorithm

## Algorithm: BINARY\_SEARCH

**Input:** An array  $A[1..n]$  of  $n$  elements sorted in non-decreasing order and an element  $x$ .

**Output:**  $j$  if  $x = A[j]$ ,  $1 \leq j \leq n$ , and 0 otherwise.

```
1.  $low = 1; high = n; j = 0$ 
2. while ( $low \leq high$ ) and ( $j = 0$ )
3.    $mid = \lfloor (low + high) / 2 \rfloor$ 
4.   if  $x = A[mid]$  then  $j = mid$ 
5.   else if  $x < A[mid]$  then  $high = mid - 1$ 
6.   else  $low = mid + 1$ 
7. end while
8. return  $j$ 
```

Can be considered  
as one comparison
